# nag\_mv\_discrim\_mahaldist (g03dbc)

## 1. Purpose

nag\_mv\_discrim\_mahaldist (g03dbc) computes Mahalanobis squared distances for group or pooled variance-covariance matrices. It is intended for use after nag\_mv\_discrim (g03dac).

## 2. Specification

## 3. Description

Consider p variables observed on  $n_g$  populations or groups. Let  $\bar{x}_j$  be the sample mean and  $S_j$  the within-group variance-covariance matrix for the jth group and let  $x_k$  be the kth sample point in a data set. A measure of the distance of the point from the jth population or group is given by the Mahalanobis distance,  $D_{kj}^2$ :

$$D_{kj}^{2} = (x_k - \bar{x}_j)^T S_j^{-1} (x_k - \bar{x}_j).$$

If the pooled estimated of the variance-covariance matrix S is used rather than the within-group variance-covariance matrices, then the distance is:

$$D_{kj}^2 = (x_k - \bar{x}_j)^T S^{-1} (x_k - \bar{x}_j).$$

Instead of using the variance-covariance matrices S and  $S_j$ , nag\_mv\_discrim\_mahaldist uses the upper triangular matrices R and  $R_j$  supplied by nag\_mv\_discrim (g03dac) such that  $S = R^T R$  and  $S_j = R_j^T R_j$ .  $D_{kj}^2$  can then be calculated as  $z^T z$  where  $R_j z = (x_k - \bar{x}_j)$  or  $Rz = (x_k - \bar{x}_j)$  as appropriate.

A particular case is when the distance between the group or population means is to be estimated. The Mahalanobis distance between the ith and jth groups is:

$$D_{ij}^{2} = (\bar{x}_{i} - \bar{x}_{j})^{T} S_{j}^{-1} (\bar{x}_{i} - \bar{x}_{j})$$

or

$$D_{ij}^2 = (\bar{x}_i - \bar{x}_j)^T S^{-1} (\bar{x}_i - \bar{x}_j).$$

**Note:**  $D_{jj}^2 = 0$  and that in the case when the pooled variance-covariance matrix is used  $D_{ij}^2 = D_{ji}^2$  so in this case only the lower triangular values of  $D_{ij}^2$ , i > j, are computed.

### 4. Parameters

## equal

Input: indicates whether or not the within-group variance-covariance matrices are assumed to be equal and the pooled variance-covariance matrix used.

If equal = Nag\_EqualCovar the within-group variance-covariance matrices are assumed equal and the matrix R stored in the first p(p+1)/2 elements of gc is used.

If equal = Nag\_NotEqualCovar the within-group variance-covariance matrices are assumed to be unequal and the matrices  $R_j$ , for  $j=1,2,\ldots,n_g$ , stored in the remainder of gc are used.

Constraint:  $equal = Nag\_EqualCovar$  or  $Nag\_NotEqualCovar$ .

[NP3275/5/pdf] 3.g03dbc.1

#### mode

Input: indicates whether distances from sample points are to be calculated or distances between the group means.

If  $mode = Nag\_SamplePoints$  the distances between the sample points given in x and the group means are calculated.

If mode = Nag\_GroupMeans the distances between the group means will be calculated.

Constraint: mode = Nag\_SamplePoints or Nag\_GroupMeans.

#### nvar

Input: the number of variables, p, in the variance-covariance matrices as specified to nag\_mv\_discrim (g03dac).

Constraint:  $\mathbf{nvar} \geq 1$ .

#### ng

Input: the number of groups,  $n_q$ .

Constraint:  $ng \geq 2$ .

## gmean[ng][tdg]

Input: the jth row of **gmean** contains the means of the p selected variables for the jth group, for  $j = 1, 2, ..., n_a$ . These are returned by nag\_mv\_discrim (g03dac).

### tdg

Input: the last dimension of the array **gmean** as declared in the calling program.

Constraint:  $\mathbf{tdg} \geq \mathbf{nvar}$ .

## gc[(ng+1)\*nvar\*(nvar+1)/2]

Input: the first p(p+1)/2 elements of  ${\bf gc}$  should contain the upper triangular matrix R and the next  $n_g$  blocks of p(p+1)/2 elements should contain the upper triangular matrices  $R_j$ . All matrices must be stored packed by column. These matrices are returned by nag\_mv\_discrim (g03dac). If  ${\bf equal} = {\bf Nag\_EqualCovar}$  only the first p(p+1)/2 elements are referenced, if  ${\bf equal} = {\bf Nag\_NotEqualCovar}$  only the elements p(p+1)/2 to  $(n_g+1)p(p+1)/2-1$  are referenced. Constraints:

If equal = Nag\_EqualCovar the diagonal elements of  $R \neq 0.0$ .

If equal = Nag\_NotEqualCovar the diagonal elements of the  $R_j \neq 0.0$ , for  $j = 1, 2, \dots, ng$ .

## nobs

Input: if  $mode = Nag\_SamplePoints$  the number of sample points in x for which distances are to be calculated. If  $mode = Nag\_GroupMeans$ , nobs is not referenced.

Constraint: if  $mode = Nag\_SamplePoints$ ,  $nobs \ge 1$ .

 $\mathbf{m}$ 

Input: if  $mode = Nag\_SamplePoints$  the number of variables in the data array x. If  $mode = Nag\_GroupMeans$ , then m is not referenced.

Constraint: if  $mode = Nag\_SamplePoints$ ,  $m \ge nvar$ .

## isx[m]

Input: if  $\mathbf{mode} = \mathbf{Nag\_SamplePoints}$ ,  $\mathbf{isx}[l-1]$  indicates if the lth variable in  $\mathbf{x}$  is to be included in the distance calculations. If  $\mathbf{isx}[l-1] > 0$ , the lth variable is included, for  $l = 1, 2, ..., \mathbf{m}$ ; otherwise the lth variable is not referenced.

If **mode** = **Nag\_GroupMeans**, then **isx** is not referenced and may be set to the NULL pointer (Integer \*)0.

Constraint: if **mode** = Nag\_SamplePoints, isx[l-1] > 0 for **nvar** values of l.

## x[nobs][tdx]

Input: if  $\mathbf{mode} = \mathbf{Nag\_SamplePoints}$  the kth row of  $\mathbf{x}$  must contain  $x_k$ . That is,  $\mathbf{x}[k-1][l-1]$  must contain the kth sample value for the lth variable for  $k=1,2,\ldots,\mathbf{nobs};\ l=1,2,\ldots,\mathbf{m}$ . Otherwise  $\mathbf{x}$  is not referenced and may be set to the NULL pointer (double \*)0.

3.g03dbc.2 [NP3275/5/pdf]

#### tdx

Input: the last dimension of the array  $\mathbf{x}$  as declared in the calling program. Constraint:  $\mathbf{tdx} \ge \max(1, \mathbf{m})$ .

## d[dim1][tdd]

Output: the squared distances.

If **mode** = Nag\_SamplePoints,  $\mathbf{d}[k-1][j-1]$  contains the squared distance of the kth sample point from the jth group mean,  $D_{kj}^2$ , for  $k=1,2,\ldots,$ **nobs**;  $j=1,2,\ldots,n_q$ .

If mode = Nag\_GroupMeans and equal = Nag\_NotEqualCovar,  $\mathbf{d}[i-1][j-1]$  contains the squared distance between the ith mean and the jth mean,  $D_{ij}^2$ , for  $i=1,2,\ldots,n_g$ ;  $j=1,2,\ldots,i-1,i+1,\ldots,n_g$ . The elements  $\mathbf{d}[i-1][i-1]$  are not referenced for  $i=1,2,\ldots,n_g$ .

If  ${f mode} = {f Nag\_GroupMeans}$  and  ${f equal} = {f Nag\_EqualCovar}, \ {f d}[i-1][j-1]$  contains the squared distance between the ith mean and the jth mean,  $D^2_{ij}$ , for  $i=1,2,\ldots,n_g$ ;  $j=1,2,\ldots,i-1$ . Since  $D_{ij}=D_{ji}$  the elements  ${f d}[i-1][j-1]$  are not referenced, for  $i=1,2,\ldots,n_g$ ;  $j=i,i+1,\ldots,n_g$ .

Constraint: dim1 must be  $\geq$  **nobs** if **mode** = **Nag\_SamplePoints**, otherwise dim1 must be  $\geq$  **ng**.

### tdd

Input: the last dimension of the array  $\mathbf{dd}$  as declared in the calling program.

Constraint:  $\mathbf{tdd} \geq \mathbf{ng}$ .

fail

The NAG error parameter, see the Essential Introduction to the NAG C Library.

## 5. Error Indications and Warnings

#### NE\_BAD\_PARAM

On entry, parameter equal had an illegal value.

On entry, parameter **mode** had an illegal value.

#### NE\_INT\_ARG\_LT

On entry, **nvar** must not be less than 1:  $\mathbf{nvar} = \langle value \rangle$ .

On entry, **ng** must not be less than 2:  $\mathbf{ng} = \langle value \rangle$ .

## NE\_2\_INT\_ARG\_LT

On entry,  $\mathbf{tdg} = \langle value \rangle$  while  $\mathbf{nvar} = \langle value \rangle$ .

These parameters must satisfy  $tdg \ge nvar$ .

On entry,  $\mathbf{tdd} = \langle value \rangle$  while  $\mathbf{ng} = \langle value \rangle$ .

These parameters must satisfy  $\mathbf{tdd} \geq \mathbf{ng}$ .

### NE\_INT\_ARG\_ENUM\_CONS

On entry,  $nobs = \langle value \rangle$  while  $mode = Nag\_SamplePoints$ .

These parameters must satisfy  $nobs \ge 1$  when  $mode = Nag\_SamplePoints$ .

## NE\_2\_INT\_ARG\_ENUM\_CONS

On entry,  $\mathbf{m} = \langle value \rangle$  while  $\mathbf{nvar} = \langle value \rangle$  and  $\mathbf{mode} = \mathbf{Nag\_SamplePoints}$ .

These parameters must satisfy  $m \ge nvar$  when  $mode = Nag\_SamplePoints$ .

On entry,  $\mathbf{tdx} = \langle value \rangle$  while  $\mathbf{m} = \langle value \rangle$  and  $\mathbf{mode} = \mathbf{Nag\_SamplePoints}$ .

These parameters must satisfy  $\mathbf{tdx} \ge \max(1,\mathbf{m})$  when  $\mathbf{mode} = \mathbf{Nag\_SamplePoints}$ .

## NE\_VAR\_INCL\_COND

The number of variables, **nvar** in the analysis =  $\langle value \rangle$ , while number of variables included in the analysis via array **isx** =  $\langle value \rangle$ .

Constraint: These two numbers must be the same when **mode** = **Nag\_SamplePoints**.

## NE\_DIAG\_0\_COND

A diagonal element of R is zero when equal = Nag\_EqualCovar.

#### NE\_DIAG\_0\_J\_COND

A diagonal element of R is zero for some j, when equal = Nag\_NotEqualCovar.

[NP3275/5/pdf] 3.g03dbc.3

### NE\_ALLOC\_FAIL

Memory allocation failed.

### NE\_INTERNAL\_ERROR

An internal error has occurred in this function. Check the function call and any array sizes. If the call is correct then please consult NAG for assistance.

### 6. Further Comments

If the distances are to be used for discrimination, see also nag\_mv\_discrim\_group (g03dcc).

### 6.1. Accuracy

The accuracy will depend upon the accuracy of the input R or  $R_i$  matrices.

## 8. Example

The data, taken from Aitchison and Dunsmore (1975), is concerned with the diagnosis of three 'types' of Cushing's syndrome. The variables are the logarithms of the urinary excretion rates (mg/24hr) of two steroid metabolites. Observations for a total of 21 patients are input and the group means and R matrices are computed by nag\_mv\_discrim (g03dac). A further six observations of unknown type are input, and the distances from the group means of the 21 patients of known type are computed under the assumption that the within-group variance-covariance matrices are not equal. These results are printed and indicate that the first four are close to one of the groups while observations 5 and 6 are some distance from any group.
