- Transient changes in c_s can consistently imprint on relatively much shorter scales (beyond CMB scales) \rightarrow might be detected with far superior statistics if they are really there.
- From the perspective of the EFT of inflation, transient changes in c_s occur very naturally– encode the influence of heavy fields on the dynamics of the adiabatic mode *completely consistent with decoupling, adiabaticity, the persistence of slow roll, and the validity of the single field regime.* Achucarro, SP et al. 2010- 2012

What do adiabatic correlators know about the background?

Up to two derivatives, the quadratic action is a function of only two independent functions, $\epsilon=-\dot{H}/H^2$ and c_s .

- $S_{(2)} = \int d^4 x \, \epsilon \, a^3 \left(\frac{1}{c_s^2} \dot{\mathcal{R}}^2 (\nabla \mathcal{R})^2 \right)$
- Where e.g. $c_s^{-2} = 1 \frac{2M_2^4}{M_{pl}^2\dot{H}}$;
- ... because \mathcal{R} is conserved on super-horizon scales. i.e. $\mathcal{R}^{\mathbb{Z}}$, $\dot{\mathcal{R}}\mathcal{R}$
- Similarly, at cubic order we have six possible operators: δN^3 , $\delta N^2 \delta E_i^i$, $\delta N (\delta E_i^i)^2$, $\delta N \delta E^{ij} \delta E_{ij}$, $(\delta E_i^i)^3$, $\delta E_i^i \delta E^{ij} \delta E_{ij}$.
- But the cubic action depends only on four independent functions– the coefficients of: R³, R²R, R(∇R)², R(∇R)², R³
- Moreover, if $\mathcal{L}_m = \mathcal{L}_m(\phi, \nabla \phi)$, then in unitary gauge, shift vector can't appear in matter Lagrangian. Only δN^m appears.
- Action up to cubic order depends only on \dot{H}, M_2^4, M_3^4 .
- $M_3^4 = \# M_2^4 (1 c_s^2)$ Chen et al hep-th/0605045; Achucarro, Hardeman, Gong, Palma, Patil 1201.6342 True under very general assumptions Senatore, Smith, Zaldarriaga arXiv:0905.3746
- All coefficients in the EFT expansion depend only on ϵ , c_s^2 , and their derivatives.

Introduction OO	BSM Cosmology OO	Features as cosmological probes	Correlated Features
Conclusions			

- The positive detection of such (correlated) features in future data sets would help us better understand the true nature of the inflaton.
- Features induced by varying c_s can in principle, be imprinted on very short scales (where the statistics for their detection improve markedly).

| Conclusions | | | |

Prominent features could be imprinted onto primordial observables, whose correlations at commensurate scales encode the embedding of inflation into some parent theory.

- The positive detection of such (correlated) features in future data sets would help us better understand the true nature of the inflaton.
- Features induced by varying c_s can in principle, be imprinted on very short scales (where the statistics for their detection improve markedly).
- Encode the influence on heavy fields on the dynamics of the adiabatic mode.
- In principle, a primitive spectroscopy.
- In combination with other statistics, can tell us about the universality class of effective Lagrangians that resulted in inflation.
